# STATISTICAL DATA ANALYSIS and MACHINE LEARNING

July 14, 2020

# 1 INTRODUCTION AND SUMMARY

Machine learning models are based on statistics, optimization and computer science. Our project aims to compare the performance of a few machine learning models on different databases. For this analysis, we used the Python programming language on Jupyter notebooks. The project will be realized in 2 terms and we conducted the experimental part in our first period. We will present the theoretical discussion of mathematical basis of the models use in the fall period of 2021.

# 1.1 PROJECT PLAN

# 1.1.1 Aim of the Project

We aim to perform rigorous statistical analysis of 6 different machine learning models on 3 different datasets.

# 1.1.2 Scope of the Project

Within the scope of this project, 6 different machine learning models were selected from well-known and commonly used python libraries. A deeper theoretical exploration about the models will be given at the thesis stage. Since we have devoted our first period to experiments, we will show an explanatory code section of the project in this report.

# 1.1.3 Area of Usage

Within the scope of the analysis, the final version of the project can be used as a resource for those who want to learn the mathematical background of machine learning models, and how they can be applied to real-world data sets. We aim that the thesis will be a resource for those who want to learn from the beginning which models work best for which dataset.

# 1.1.4 Schedule

Task	Alloted Time
Research and discovery of databases	2 weeks
Clearing and preparing datasets	2 weeks
Determining the models and libraries to be used	1 week
Coding phase and evaluation of outputs	10 weeks
General arrangement of the code stage and annotation	2 weeks
Writing the report	3 weeks

#### 1.1.5 Resources

All databases, libraries and models used are open source. All relevant references will be made to the books, articles and theses used for theory in the reference section in the thesis section. All work is stored on github. (https://github.com/Code-Cash/ahmet)

# 2 EXPERIMENTS

Our project is based on a through and rigorous statistical analysis of 6 different machine learning algorithms over 3 databases.

The code block you see below is the experimental stage of this thesis. We give descriptions about each cell just above the corresponding cell.

# 2.1 Loading the libraries

At the beginning of our project, we need to add the libraries required for our project.

```
[2]: import pandas as pd
     import numpy as np
     from pandas import Series, DataFrame
     from sklearn.preprocessing import scale
     from sklearn.model_selection import cross_val_score
     from sklearn import tree
     from sklearn.tree import DecisionTreeClassifier
     from sklearn.linear_model import LogisticRegression
     from sklearn.svm import SVC
     from sklearn.ensemble import RandomForestClassifier
     from sklearn.model_selection import train_test_split
     from sklearn.metrics import classification_report
     from sklearn.metrics import confusion_matrix
     from PIL import Image
     from sklearn.metrics import accuracy_score
     import statsmodels.api as sm
     from statsmodels.formula.api import ols
     from statsmodels.stats.anova import AnovaRM
     from matplotlib import pyplot as plt
     from matplotlib import pyplot
     import seaborn as sns
     import xgboost as xgb
     from sklearn.naive bayes import GaussianNB
     from xgboost import XGBClassifier
     from sklearn.model_selection import train_test_split
     from sklearn.metrics import accuracy_score
     from sklearn.feature_selection import RFE
```

# 2.2 Loading the models

We load 6 blank machine learning models after adding our libraries.

```
[3]: dt = DecisionTreeClassifier()
    rf = RandomForestClassifier(n_estimators=100, random_state=0, n_jobs = -1)
    logreg = LogisticRegression(solver='liblinear',multi_class='ovr')
    svm = SVC(gamma='auto')
    xgb = xgb.XGBClassifier()
    gnb = GaussianNB()
```

# 2.3 Loading the first data set

We add our first data set using the pandas library. Then we display the first 5 elements of our dataset using the panda's head function.

```
[5]: database1 = pd.read_csv("data.csv", sep=';')
     database1.head()

# 2.4 Feature selection and splitting the train and test data sets

Let us denote the features we are going to use with X and response variable with y. With the drop function, we get the columns other than the columns 'musk' and '168'. For the response variable, we just take the column named '168'. Then we determine the size of our training and test sets. For this dataset, 90% of all data is used for training and the remaining 10% is used for testing using the function "train test split".

```
[7]: X = database1.drop(["MUSK","168"],axis=1)
y = database1['168']
X_train, X_test, y_train, y_test = train_test_split(X, y,test_size=0.10)
```

# 2.5 A generic function for training and evaluating a model

At this stage, we create a function that will run our 6 algorithms for our first dataset and give us 3 outputs.

If we go into detail: first, we train our model with the features X, which is the training group we mentioned in Section 4, with the features in y as dependent variable. Then we make a prediction with the predict function according to the test data set. We record this prediction as y\_pred. The test data set y\_test is the test set of the results will give us the accuracy of the model. Then we print the classification report and confusion matrix with the help of the scikit-learn library. The explanation of all these functions will be found in the theory section of our thesis.

```
[4]: def model(name, X_train, y_train, X_test, y_test):
    name.fit(X_train, y_train)
    y_pred = name.predict(X_test)
    score= accuracy_score(y_test, y_pred) * 100
    print(str(name) + "Accuracy:",score)
    report_name=classification_report(y_test, y_pred)
    print(report_name)
    print(confusion_matrix(y_test,y_pred))
```

#### 2.6 Recursive Feature Elimination

The purpose of the function below is to find the most suitable features for us in our database. The rfe (Recursive Feature Elimination) function produces an output based on the model we want and the number of desired features. It shows them in order, according to their effect.

```
[5]: def rfe(model,X,y):
    rfe = RFE(model, 16)
    fit = rfe.fit(X, y)
    print("Num Features: %s" % (fit.n_features_))
    print("Selected Features: %s" % (fit.support_))
    print("Feature Ranking: %s" % (fit.ranking_))
```

#### 2.7 Cross validation

Cross validation calculates the average accuracy and standard deviation for each part by dividing our data into as many parts as we want. This gives us an important idea of how well the model works.

```
[6]: def crossval(model,X,y,n=10):
    scores=cross_val_score(model, X, y, cv=n, scoring ="accuracy")
    print(str(model) + "Accuracy: %0.2f (+/- %0.2f)" % (scores.mean(), scores.

→std() * 2))
```

# 2.8 Experiments on the first data set

#### 2.8.1 Decision Tree

Let us evaluate the Decision Tree model on our first data set.

```
[15]: model(dt,X_train,y_train,X_test,y_test)
    crossval(dt,X,y,n)
    rfe(dt,X,y)
```

# 2.9.1 Train and Test Split

At this stage, we already have separate test and train subsets, and as a result, we do not need to use the train\_test\_split function we uses for the first dataset. Because currently our training and test sets are already given. All we have to do is to assign the independent and dependent variables.

```
[10]: X1_train = database2.drop(["d"], axis=1)
X1_test = database3.drop(["d"], axis=1)
y1_train = database2['d']
y1_test = database3['d']
```

# 2.9.2 Combining Train and Test for Cross-Validation

This stage is actually combining the operations we did in stage 9, the two datasets above and then assigning the properties as df\_row\_reindex\_X and the results as df\_row\_reindex\_y. As a result, it allows us to work with a single dataset, not two. We do this with the function named concat in the pandas library.

```
[11]: df_row_reindex = pd.concat([database2, database3], ignore_index=True)
    df_row_reindex_X = df_row_reindex.drop(["d"], axis=1)

# 2.10.1 Feature selection and splitting the train and test data sets

Let us denote the features we are going to use with X and response variable with y. With the drop function, we get the columns other than the columns 'MESANE-ILTIHABI' and 'BOBREK-ILTIHABI'. For the response variable, we just take the column named 'MESANE-ILTIHABI'. Then we determine the size of our training and test sets. For this dataset, 80% of all data is used for training and the remaining 20% is used for testing using the function "train\_test\_split".

```
[50]: X = db.drop(["MESANE-ILTIHABI", "BOBREK-ILTIHABI"], axis=1)
y = db['MESANE-ILTIHABI']
X_train, X_test, y_train, y_test = train_test_split(X, y,test_size=0.2)

[51]: A = db.drop(["MESANE-ILTIHABI", "BOBREK-ILTIHABI"], axis=1)
b = db['BOBREK-ILTIHABI']

```

# 2.10.2 Create array for loop

We create two arrays for our third dataset. We will use these arrays for the functions we will write below. The difference between the two arrays is that the rfe function does not work in SVM and GNB algorithms.

```
[]: models = [dt, rf, logreg, svm, xgb, gnb]
```

#### 2.10.3 Evaluate Models

Let us evaluate the all model on our third data set.

```
[85]: for i in models:
          model(i, X_train, X_test, y_train, y_test)
          model(i, A_train, A_test, b_train, b_test)
          crossval(i, X, y, 5)
          crossval(i, X, y, 10)
          crossval(i, A, b, 5)
          crossval(i, A, b, 10)
